ABSTRACT

Studies on the food composition of an unexploited species, bleak, was carried out in 1984 and 1985 in the Włocławek Dam Reservoir. Biomass of the food components was estimated basing on organism length and weight standards.

Cladocera (mostly *Daphnia* sp.) and *Chironomidae* pupae, and imagines represented basic food items of this species.

Diet composition suggests that the bleak penetrates whole column of water, from surface to the bottom.
